

Database Schema

1. Use docker exec command to run "rag-postgres" to enter the postgres
2. Enable pgvector extension using the create extension if not exists command

```
C:\Users\sanja>docker exec -it rag-postgres psql -U postgres
psql (16.14 (Debian 16.14-1.pgdg12+1))
Type "help" for help.
```

```
postgres=# create extension if not exists vector;
CREATE EXTENSION
```

3. Create table with the following schema:
 - a. id: auto incrementing primary key variable
 - b. d_name: string that stores document name(null value not permitted)
 - c. chunk_text: result from chunking is stored here as text
 - d. created_at: useful for version control
 - e. embedding: array that accepts 384 numbers; sentence transformer model(sentence-transformers/paraphrase-multilingual-MiniLM-L12-v2) returns an array of 384 numerical values

```
postgres=# create table if not exists docs (
id Serial primary key,
d_name varchar(255) not null,
chunk_text text not null,
created_at timestamp default current_timestamp,
postgres(# embedding vector(384));
CREATE TABLE
```

```
postgres=# select * from docs;
 id | d_name | chunk_text | created_at | embedding 
----+-----+-----+-----+-----
(0 rows)
```
